Text S1. Effect of Sodium Reduction on Systolic Blood Pressure in Randomized Controlled Trials.

Two recent Cochrane meta-analyses evaluated randomized trials of sodium reduction and BP.^{1,2} One assessed 28 longer-term trials published through 2005; and the other, many more (n=167) trials but also those testing only small (<20 mmol/d reduction) or brief duration (<2 weeks) sodium reduction interventions that might not validly inform longer-term effects. Additionally, these meta-analyses did not evaluate whether BP-lowering effects were linear across a wide range of sodium reduction or simultaneously quantify potential heterogeneity owing to age, hypertensive status, race, and duration of intervention, which could each modify effects of sodium on BP.

To address these issues, we performed a new meta-analysis of the effect of dietary sodium on BP. For study identification, we included all randomized controlled trials of sodium reduction identified in these two prior meta-analyses. After excluding 5 trials with missing data on quantity of sodium reduction, mean age, or duration, we identified 160 trials including 169 group comparisons. Of these, 57 trials with 62 group comparisons had duration<7 days, mean sodium reduction<20 mmol/d, or concurrent interventions that were not balanced between groups. In prespecified primary analyses, we evaluated the remaining 103 trials that included 107 group comparisons, totaling 6,970 subjects. Sodium reductions ranged from 23 to 285 (mean±SD: 99±55) mmol/d, intervention durations from 7 to 1100 (mean±SD: 65±160) days, and mean subject age from 13 to 73 (mean±SD: 47.4±14.4) y. About two-thirds (64.5%) of comparisons were in hypertensive subjects; and 9.3% in Black subjects. In sensitivity analyses, we evaluated all 160 trials including 169 group comparisons, totaling 9,606 subjects. Sodium reductions ranged from 16 to 341 (mean±SD: 119±74) mmol/d, intervention durations from 4 to 1100 (mean±SD: 53±136) days, and mean subject age from 13 to 73 (mean±SD: 43.6±14.8) y.

We first evaluated whether effects of sodium reduction on BP were linear, using semi-parametric restricted cubic spline regression with 4 knots (mkspline command in Stata), adjusting for age (years), hypertensive status (yes/no), and race (Black, non-Black) and weighting each study by the inverse of its variance. In the primary analysis of 107 randomized group comparisons, there was strong evidence for a linear effect (P linearity<0.001) and no significant evidence for a nonlinear effect (P nonlinearity=0.58) (**Figure 1**, **main manuscript**). Findings were similar if we included all 169 randomized comparisons (P linearity<0.001; P

nonlinearity=0.84). Evaluated using inverse-variance weighted meta-regression, each 100 mmol/d reduction lowered BP by 3.82 mm Hg (95% CI: 3.08, 4.55).

We evaluated potential heterogeneity in this effect by jointly considering population characteristics including age, hypertensive status, race, and study duration using inverse variance-weighted meta regression with each trial standardized to 100 mmol/d (2.3 g/d sodium, 5.85 g/d salt) sodium reduction. We identified significant independent interaction by age (**Figure S2**), hypertensive status, and race (P-interaction<0.001, 0.036, and 0.039, respectively), but not study duration (P-interaction=0.88). The final meta-regression equation (metareg command in Stata) was $Y = \alpha + B_1X_1 + B_2X_2 + B_3X_3$, where Y = the BP change in each trial in mm Hg, standardized to a sodium reduction of 100 mmol/d; B₁ = the mean age of subjects in each trial in years, centered at age 50; B_2 = whether the trial was conducted in normotensive or hypertensive subjects; B_3 = whether the trial was conducted in non-Blacks or Blacks; and α = the effect of a 100 mmol/d sodium reduction on systolic BP when mean subject age=50, subjects were normotensive, and subjects were not Black. Each trial was weighted by the inverse variance of its BP change, standardized to a sodium reduction of 100 mmol/d. The final coefficients (SE) were: $\alpha = -3.735 (0.730)$; $B_1 = -0.105 (0.029)$; $B_2 = -1.874 (0.884)$; and $B_3 = -2.489 (1.188)$. In other words, for a white, normotensive population at age 50, each 100 mmol/d sodium reduction lowered systolic BP by 3.74 mm Hg (95%CI: 2.29, 5.18). For every year above or below age 50, there was 0.105 mm Hg (95%CI: 0.047, 0.164) larger or smaller BP reduction, respectively: e.g., for normotensives at age 25, a 100 mmol/d reduction lowered BP by 1.12 mm Hg (3.74 - 25 yrs*0.105/yr); and at age 70, by 5.84 mm Hg (3.74 + 25 yrs*0.105/yr); 20 yrs*0.105/yr). Additionally, there was 2.49 mm Hg greater reduction among Blacks (95%CI: 0.13, 4.85), and 1.87 mm Hg greater reduction among hypertensives (95%CI: 0.12, 3.63).

Similar findings were seen when using all 169 randomized comparisons, with joint interactions by age, hypertension, and race (P-interaction<0.001, 0.004, and 0.007, respectively). For a white, normotensive population at age 50, 100 mmol/d lower sodium intake reduced systolic BP by 3.39 mm Hg (95%CI: 2.31, 4.47). For every year above or below age 50, there was 0.124 mm Hg (95%CI: 0.079, 0.169) larger or smaller BP reduction, respectively. Further, BP reduction was 1.90 mm Hg greater among hypertensives (95%CI: 0.61, 3.20), and 2.49 mm Hg greater among Blacks (95%CI: 0.68, 4.30).

We also considered evidence for whether, separately from hypertensive status, BP-lowering effects of sodium reduction were blunted by anti-hypertensive medication use. In one of the meta-analyses used to identify trials of sodium reduction, none of the subjects were on anti-hypertensives; in the other meta-analysis, trials in which subjects were taking anti-hypertensives were not excluded but this characteristic was not coded, precluding formal evaluation of heterogeneity. In addition, several trials have demonstrated significant BP-lowering effects of sodium restriction among patients taking anti-hypertensive drugs, often with large BP responses. In addition, a few trials found that BP-lowering effects of sodium restriction were similar in subjects taking or not taking anti-hypertensives. Although not definitive due to the limited number of studies, together this evidence provided little support for a substantial blunting of BP-lowering effects of sodium restriction by use of anti-hypertensive drugs.

Text S2. Effects of Blood Pressure on Deaths from Cardiovascular Diseases

The dose-response relationship between BP and CVD mortality has been established in prior pooling projects including the Prospective Studies Collaborative and the Asia Pacific Cohort Studies Collaborative.

14,15

These studies pooled individual level data across multiple prospective studies, together totaling 99 cohorts, 1.38 million participants, and 65,000 cardiovascular events; with consistent adjustment for confounders and accounting for regression dilution bias based on serial measures of BP over time. These analyses demonstrate a clear log-linear (proportional) dose-response relationship between BP and CVD at any age (Figure S3). Based on the evidence, we assumed a log-linear dose-response between BP and CVD until a BP level of 115 mm Hg, after which we assumed no further contribution to risk. To incorporate data from both prior pooling projects, we interpolated and extrapolated age-specific proportional effects (relative risks) of systolic BP on CVD mortality in 10-year age groups across the studies.
We pooled age-stratified relative risks using random effects models and quantified uncertainty using simulation analyses. The final age patterns were similar to prior estimated burdens at younger ages). Our final age-specific relative risks for various CVD conditions have been published.

16

Text S3. Consideration of Causal Effects of Sodium Reduction on CVD

Our methods for evaluating causality of diet-disease relationships, including the effects of sodium on CVD, have been reported. 18 Several prior reports have extensively reviewed the evidence for CVD effects of dietary sodium, including strengths and limitations of various studies and implications for causality. 19-26 Here, we highlight several key points. Based on prior analyses and our de novo meta-analysis (above), sodium reduction significantly lowers BP. We also found strong evidence that BP-lowering reduces CHD and stroke. A meta-analysis of 154 randomized trials of various anti-hypertensive agents and CVD events demonstrated that the effects of all major classes of anti-hypertensive drugs principally correspond to their BP-lowering.²⁷ For each class including thiazides, beta blockers, angiotensin converting enzyme inhibitors, angiotensin receptor blockers, and calcium channel blockers, the achieved risk reductions for CHD and stroke in the trials were very similar to the predicted benefits based on their BP-lowering, based on the observed association between BP and CVD risk in prospective cohorts. 14 Beta blockers had a larger effect above and beyond that due to BP reduction only for preventing recurrent CHD events in patients with a history of CHD, and also only limited to the first few years after acute myocardial infarction. These findings indicated that benefits of multiple classes of BPlowering drugs correspond to the BP reduction itself. In addition, the proportional (relative risk) reductions in CHD and stroke events were similar in people with and without pre-existing CVD and regardless of BP levels prior to treatment (down to 110 mm Hg systolic and 70 mm Hg diastolic).²⁷ In our analysis, we assumed CVD benefits down to a systolic BP of 115 mm Hg, but no further. 16

We considered whether sodium reduction might have any physiologic harms or benefits, beyond the intermediate-term effects on lowering BP, that might reduce or augment its effects. A meta-analysis of 37 trials demonstrated no significant adverse effects of sodium restriction on blood lipids, catecholamine levels, or renal function.²⁵ In terms of other physiologic effects, a large body of ecologic and experimental evidence suggests that chronically high dietary sodium may increase BP to a greater extent than short- or intermediate-term intake²⁸ and also induce other, BP-independent effects, for example increasing myocardial, arterial, and renal fibrosis and dysfunction.^{29,30} Thus, we concluded that other physiologic effects of sodium reduction, at least to modest levels (2 g/d), would be predicted to produce larger, not smaller, benefits. We did not incorporate these other potential benefits into our analysis, which could lead to underestimation of the attributable deaths.

The evidence for direct relationships between sodium intake and CVD events included reports of longterm follow-up from modestly sized randomized trials and meta-analyses of large prospective observational cohorts of sodium intakes (assessed by urine collection or diet questionnaire) and CVD events. The largest trials in general populations with long-term follow-up were TOHP I (N=744) and TOHP II (N=2.382), in which subjects were randomized to control or a sodium reduction intervention.³¹ Net sodium reductions were 44 and 33 mmol/24 h in TOHP I and TOHP II, respectively; with interventions durations of 18 mo and 36-48 mo. Posthoc long term follow-up was assessed in 2.415 subjects (77%) 10-15 v after the original trials. Risk of CVD was 30% lower in the intervention group vs. control (RR=0.70, 95%CI: 0.53, 0.94), adjusted for trial, clinic, age, sex, race, and baseline sodium excretion and weight. A meta-analysis of prospective cohorts found that higher sodium intake was associated with higher risk of total stroke (10 cohorts; RR=1.24, 95%CI: 1.08, 1.43), stroke death (3 cohorts; RR=1.63, 95%CI: 1.27, 2.10), and CHD death (3 cohorts; RR=1.32, 95%CI: 1.13, 1.53), but not total CHD (6 cohorts; RR=1.04, 95%CI: 0.86, 1.24). We recognized that urine collections and diet questionnaires provide reasonable estimates of overall mean intakes in populations and population subgroups, but poorly measure intakes in individual people due to intrinsic measurement errors, which could cause bias and/or substantial underestimation of associations with disease risk among individuals.^{32,33} For example, withinindividual variation in 24-h urine collections can be similar in magnitude to between-person variation.³⁴

A recent meta-analysis reported higher mortality with sodium reduction in trials of heart failure patients.³⁵ However, these trials, largely reported from a single Italian center, typically also included very high doses of diuretics (e.g., furosemide 500+ mg/d) that were not titrated based on subsequent volume status, with resulting marked azotemia in the patients randomized to sodium reduction. In addition, due to duplication of reported data across at least 2 of the trials, the veracity of the data has been questioned; and the investigators were unable to produce confirmatory records, leading to the retraction of the meta-analysis "on the ground that the reliability of the data on which it is based cannot be substantiated" (heart.bmj.com/content/99/11/820.2.full).

In sum, we found convincing evidence that sodium reduction lowered BP and that BP-lowering reduces CHD and stroke, at least to sodium intakes of 2 g/d and systolic BP levels of 115 mm Hg; without compelling evidence for physiologic harms. We also found consistent ecologic and experimental evidence that long-term high intakes induce additional adverse physiologic effects beyond BP; these were not incorporated into our

estimates, which might underestimate attributable disease burdens. Post-hoc analyses of trials and meta-analyses of prospective cohorts provided confirmatory evidence that the BP-lowering effects of sodium reduction translated to lower risk of CVD events, as would be expected. We agreed with a recent report²⁶ that limited information was available from studies of clinical CVD events to draw strong conclusions about additional cardiovascular benefits or harms of more substantial sodium reduction (e.g., down to 1.5 or 1.0 g/d) in either general populations or high-risk patient subgroups.

Text S4. Setting Reference Levels of Sodium Consumption

Our methods for quantifying the reference levels of sodium consumption have been described.³⁶ This distribution was selected based on the observed consumption levels associated with lowest BP in ecologic studies and in randomized trials and with lowest disease risk in meta-analyses of prospective cohort studies. We also required demonstration of at least theoretical feasibility based on observed national mean consumption levels in at least 2-3 countries globally. Finally, we considered consistency of our identified reference intakes with major dietary guidelines.

The reference levels of sodium consumption using these various definitions are shown in **Table S3**. The lowest mean intake level associated with both lower systolic BP and lower age-BP slope in ecologic studies was 614 mg/d.³⁷ In large, well-controlled, randomized feeding trials, the lowest tested intake for which BP reductions were clearly documented was 1500 mg/d.³⁸ In prospective observational studies, the lowest mean intakes associated with lower risk of CVD events ranged from 1787 to 2391 mg/d.²⁵ Because a single reference intake level considering all health outcomes is used for comparative risk assessment in overall GBD analyses, we also considered the observed mean intake levels associated with lowest risk of stomach cancer (1245 mg/d).³⁹ Thus, intake levels associated with lowest risk ranged from 614 to 2391 mg/d, depending on the type of evidence and the outcome. Based on national consumption data,⁴⁰ the lowest observed mean national intakes were ~1500 mg/d. Recommended maximum intakes in major dietary guidelines ranged from 1200 to 2400 mg/d.¹⁹⁻²⁴

Based on all available evidence, we had previously identified a reference consumption level of 1.0±0.1 g/d for our main GBD analysis evaluating all health effects including gastric cancer.¹⁷ For the present analysis

focused on CVD, we utilized a more conservative reference level of 2.0±0.2 g/d, consistent with evidence supporting health benefits of reducing high sodium intakes to moderate levels but perhaps not lower levels,²⁶ with national mean intakes in several countries, and with international WHO guidelines.

Text S5. Blood Pressure Levels by Country, Age, Sex in 2010

The methods and results for determining current blood pressure levels by country, age, and sex have been reported.⁴¹ Briefly, we obtained data from published and unpublished health examination surveys and epidemiological studies from around the world, including data from 786 country-years and 5.4 million participants. We used sex-specific Bayesian hierarchical models to estimate mean systolic BP by age, country, and year, accounting for whether each study was nationally representative. Each survey assessed current BP levels in the population, including those individuals on anti-hypertensive medication. Thus, the final estimates represent the actual mean BP in each country, by age, sex, and time, accounting for actual use of medications.

Text S6. Cause-Specific Mortality by Country, Age, and Sex in 2010

Data on BP-related cardiovascular mortality were compiled as part of the 2010 GBD study.⁴² Data were obtained on causes of death for 187 countries from 1980 to 2010 based on vital registration, verbal autopsy, mortality surveillance, censuses, surveys, hospitals, police records, and mortuaries; and assessed for completeness, diagnostic accuracy, missing data, stochastic variations, and probable causes of death. Statistical modeling strategies estimated cause-specific mortality, including different permutations of covariates and assessment of model performance with rigorous out-of-sample testing of prediction error and the validity of 95% UIs. Cause-specific fractions within each age-sex group were constrained to sum to total mortality based on draws from the uncertainty distributions. For the present analysis, we utilized data on deaths due to ischemic heart disease (ICD-10 codes I20-I25), ischemic stroke (I63, I65-I67, I69.3), hemorrhagic and other non-ischemic stroke (I60-I62, I69.0-I69.2, I67.4), hypertensive heart disease (II1-II3), aortic aneurysm (I71), rheumatic heart disease (I01, I02.0, I05-I09), endocarditis (I33), atrial fibrillation and flutter (I48), and myocarditis and cardiomyopathy (I40, I42). Only BP effects on deaths due to these conditions, not incidence, were considered.

Text S7. Modelling the Burdens of Cardiovascular Diseases Attributed to Sodium Consumption

We estimated disease burdens using comparative risk assessment framework¹⁷ that captures geographic and demographic variation in sodium intake, blood pressure, and CVD mortality, as well as corresponding uncertainties. We incorporated each country, age, and sex-specific sodium intake, BP level, relative risk, and mortality data described above to estimate the fraction and numbers of deaths attributed to sodium intake above the reference level. The population-attributable fraction (PAF) was calculated in two steps: first, based on the age-, hypertensive-, and race-specific BP effects of sodium consumption to calculate the change in mean systolic BP that would be expected from reducing sodium consumption to a reference intake of 2.0±0.2 g/d; and then based on the age-specific effects of BP on CVD to calculate the resulting change in CVD risk. No further benefits were quantified for estimated systolic BP reductions below 115 mm Hg.¹⁷

The proportion of individuals with hypertension (defined as systolic BP≥140 or diastolic BP>90 mm Hg) in each country-age-sex stratum was estimated using the model we developed based on individual-level data from 104 BP surveys in 52 countries including ~600,000 observations. Prevalence of hypertension was the dependent variable, and independent variables were mean systolic BP, age, sex, and country income. The estimated prevalence of hypertension in each stratum was used to adjust the effects of sodium intake on BP in that stratum.

The PAF was calculated across each age, sex, country, and disease-specific stratum according to the formula: $PAF = (\int RR(x)P1(x)dxmx = 0 - \int RR(x)P2(x)dxmx = 0) / \int RR(x)P1(x)dxmx = 0$; where x is the current BP level, RR(x) is the (age-specific) relative risk of each BP-related disease for a unit change in BP x, P1(x) is the population distribution of BP at current sodium levels, and P2(x) is the alternative distribution of BP if sodium consumption were at the alternative reference distribution. These calculations utilize not only the mean values of current and reference exposures, but also the population distributions (SDs) around each mean, which were predicted using coefficients from a mean-to-SD regression based on raw data. The numbers of deaths attributed to sodium intake above reference were calculated by multiplying the PAF by the absolute number of deaths rates in each country-age-sex stratum.

Uncertainty was quantified using simulation analysis, propagating the uncertainty in both exposure data and relative risks into the final mortality estimates. We drew 1,000 times from the distribution of sodium

consumption for each country-age-sex group as characterized by its mean and standard error. Independent of exposure, we generated 1,000 draws for the effects of sodium consumption on BP and the effects of BP on each disease outcome of interest, based on log normal distributions characterized by each risk estimate and its 95% confidence interval. Using these sets of 1,000 draws for the exposure and two risk estimates, we generated 1,000 estimates of the PAF and corresponding attributable number of deaths for each country-age-sex group. We derived 95% uncertainty intervals from the 2.5 and 97.5 percentiles of the resulting 1,000 estimates.

Text S8. Premature Cardiovascular Mortality Attributed to Sodium Consumption > 2 g/d

When we evaluated premature CVD deaths (before age 70), nearly 1 in 5 (17.8%) globally in 2010 were attributed to sodium intake above the reference level (95% uncertainty interval: 12.3 to 23.1%) (**Table S4**). Among all premature CVD deaths, the estimated proportion attributed to sodium was highest in upper-middle-income countries (21.6%), relatively similar in lower-middle-income countries (15.3%) and high-income countries (15.8%), and lowest in low-income countries (12.5%) (**Figure S4**).

Text S9. National Cardiovascular Mortality Attributed to Sodium Consumption > 2 g/d

Among the 30 most populous nations, highest sodium-associated CVD mortality was in Ukraine (1,540 deaths/million adults/year; 95% uncertainty interval: 1017-2099), Russia (1,316; 95% uncertainty interval: 873-1781), and Egypt (570; 95% uncertainty interval: 370-761) (**Table S5, Figure S6**). In the US, 284 CVD deaths/million adults/year (95% uncertainty interval: 184-394) were attributed to sodium above the reference level, or nearly 1 in 15 of all CVD deaths (6.3%; 95% uncertainty interval: 4.1-8.7%). Among these 30 nations, proportional sodium-associated CVD mortality was highest in China (15.3% of all CVD deaths; 95% uncertainty interval: 10.5-20.2%), Philippines (15.2 %; 95% uncertainty interval: 10.0-20.3%), and Myanmar (15.1%; 95% uncertainty interval: 10.1-20.0%). Of these CVD deaths attributed to sodium, stroke accounted for 37.6% in the Philippines, 56.1% in Myanmar, and 58.4% in China

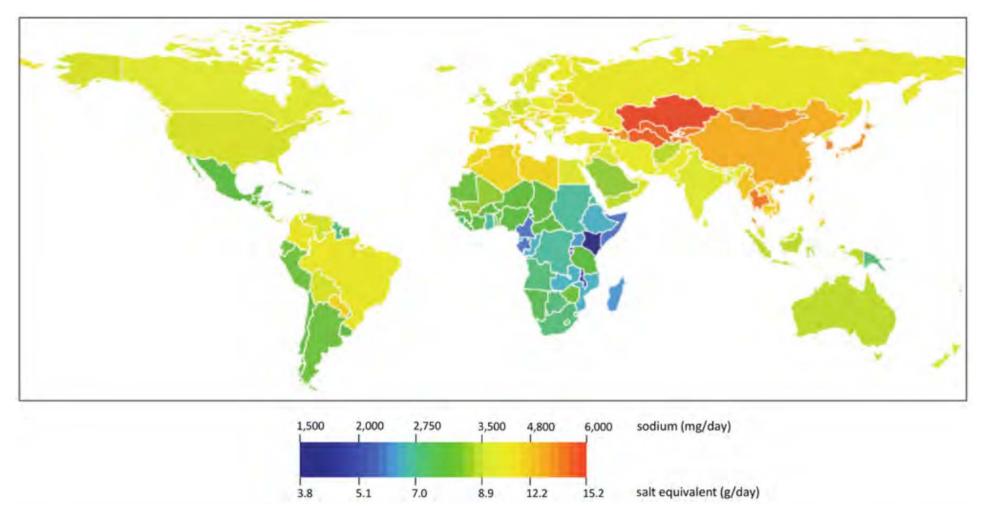

Figure S1. Mean global sodium intakes in 2010, by country. Figure reproduced with permission from Powles J et al., Global, regional, and national sodium intakes in 1990 and 2010: a systematic analysis of 24 h urinary sodium excretion and dietary surveys worldwide, BMJ Open 2013;3:e003733.

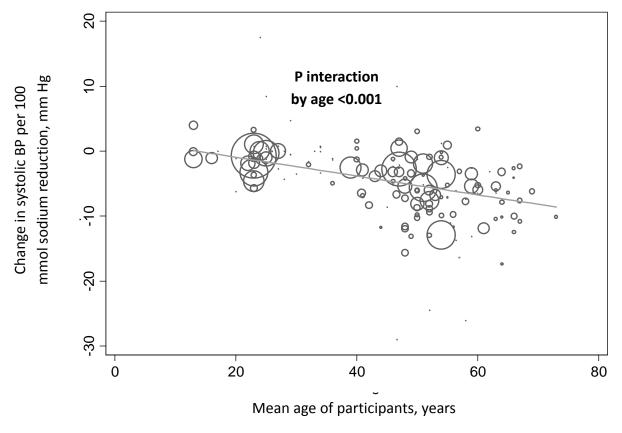

Figure S2. Effects of sodium reduction on systolic blood pressure in randomized controlled trials, by age. Based on inverse-variance weighted meta-regression of 103 trials including 107 comparisons (N=6,970 subjects). Sodium reductions ranged from 23 to 285 (mean±SD: 99±55) mmol/d, intervention durations from 7 to 1100 (mean±SD: 65±160) days, and mean subject age from 13 to 73 (mean±SD: 47.4±14.4) years. The effects of dietary sodium on BP were modified by age, with larger BP reductions among older subjects. Each circle represents one randomized comparison, with size corresponding to its inverse-variance weight; the fitted line represents the interaction by age based on random effects meta-regression. In multivariable meta-regression including age, race, and hypertensive status, effects of dietary sodium on BP were independently modified by each (P-interaction<0.001, 0.036, and 0.039, respectively). For a white, normotensive population at age 50, each 100 mmol/d sodium reduction lowered systolic BP by 3.74 mm Hg (95% CI: 2.29, 5.18). For every year above or below age 50, there was 0.105 mm Hg (95% CI: 0.047, 0.164) larger or smaller BP reduction, respectively: e.g., for normotensives at age 25, a 100 mmol/d reduction lowered BP by 1.12 mm Hg (3.74 - 25 yrs*0.105/yr); and at age 70, by 5.84 mm Hg (3.74 + 20 yrs*0.105/yr). Additionally, there was 2.49 mm Hg greater reduction among Blacks (95% CI: 0.13, 4.85), and 1.87 mm Hg greater reduction among hypertensives (95% CI: 0.12, 3.63).

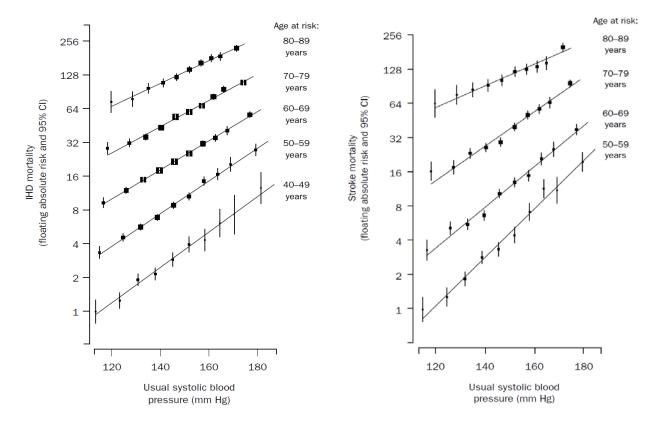

Figure S3. Dose-response relationship between systolic blood pressure and cardiovascular mortality, according to age, in one of the pooling projects utilized in our analysis. We quantified the effects of systolic blood pressure on cardiovascular mortality by combining the results from two large international pooling projects^{14,15} which pooled individual-level data, consistently adjusted for confounding, and accounted for regression dilution bias based on serial measures of blood pressure over time. 16 This Figures shows the main findings from one of these two pooling projects, based on individual-level data across 61 prospective observational studies including 958,074 participants, 12.7 million person-years of follow-up, 34,000 coronary (ischemic) heart disease (IHD) deaths, and 12,000 stroke deaths. 14 Participants were evaluated in deciles of systolic BP in 10-year age groups, with the lowest age-BP strata as the reference category. BP levels were adjusted for regression dilution bias based on serial measures over time. Adjusting for total blood cholesterol and, where available, HDL and non-HDL cholesterol, diabetes, weight, alcohol consumption, and smoking did not materially change these findings. Each square represents one age-BP stratum, with its size inversely proportional to the effective variance of the log mortality rate. The solid lines represent the fitted regression line for the relationship between BP and coronary heart disease and stroke mortality at each age. Figure adapted with permission from Lewington et al., Lancet 2002;360:1903-13.14

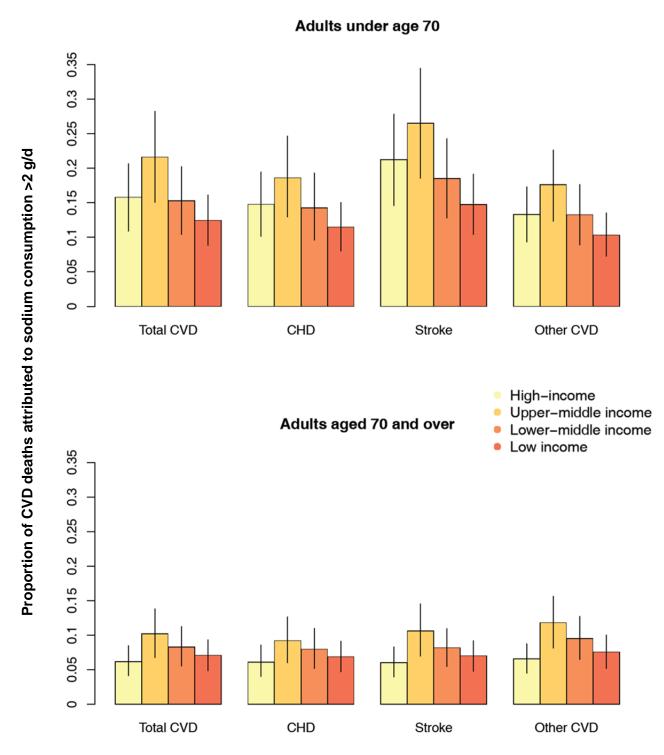

Figure S4. Proportion of CVD deaths attributed to sodium consumption >2 g/d in 2010 that occurred prematurely (before age 70 years) or after age 70 years in high, middle, and low income nations. Income categorizations were based on the country-level World Bank classification system (http://data.worldbank.org/about/country-classifications).

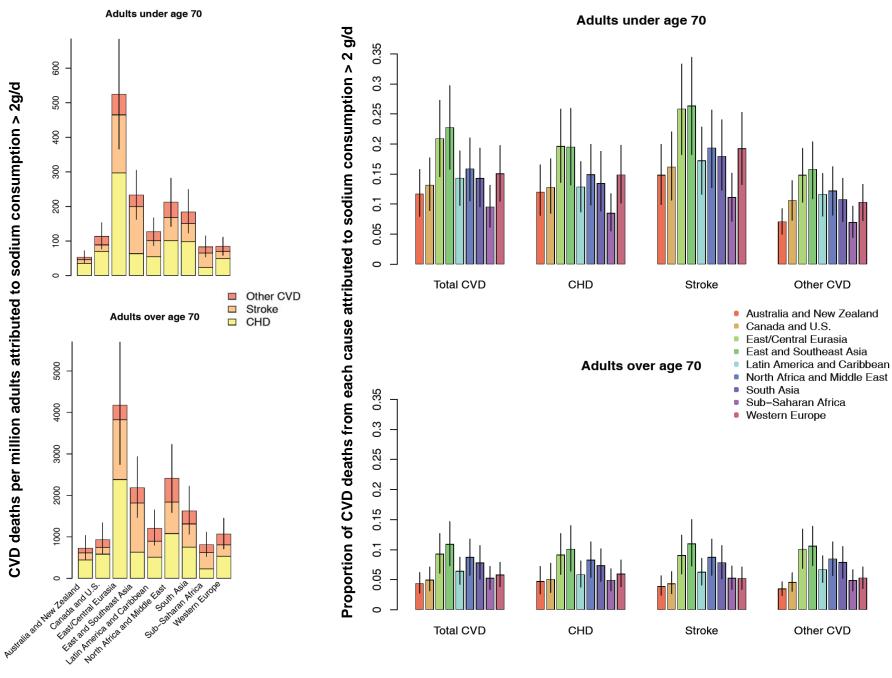

Figure S5. Absolute CVD mortality (deaths per million adults per year) and proportional CVD mortality (percent of all CVD deaths) attributed to sodium consumption >2 g/d in 2010, by age and world region.

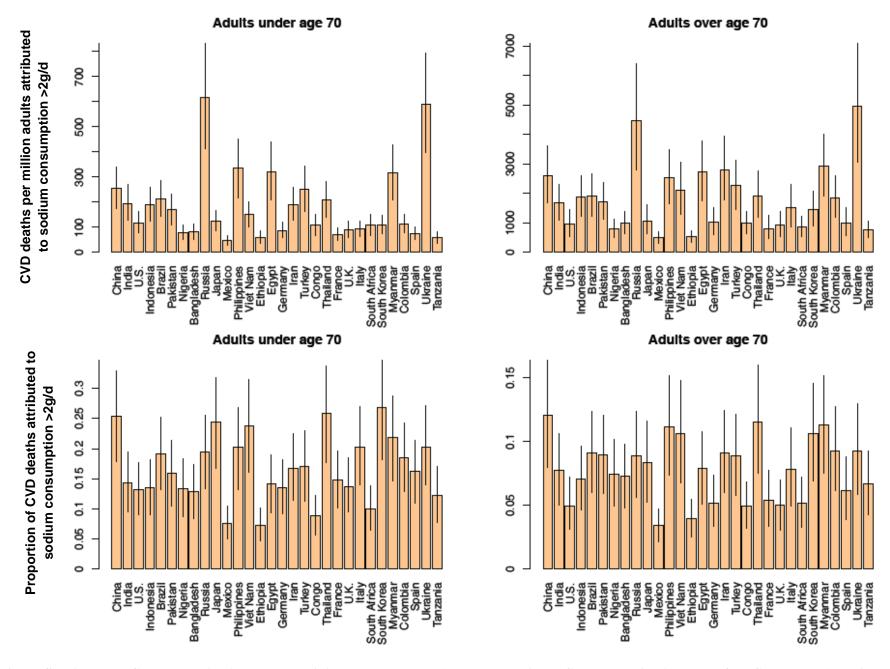

Figure S6. Absolute CVD mortality (deaths per million adults per year) and proportional CVD mortality (percent of all CVD deaths) attributed to sodium consumption >2 g/d in 2010, by age, in the world's 30 most populous nations. Countries are ordered by total population size.

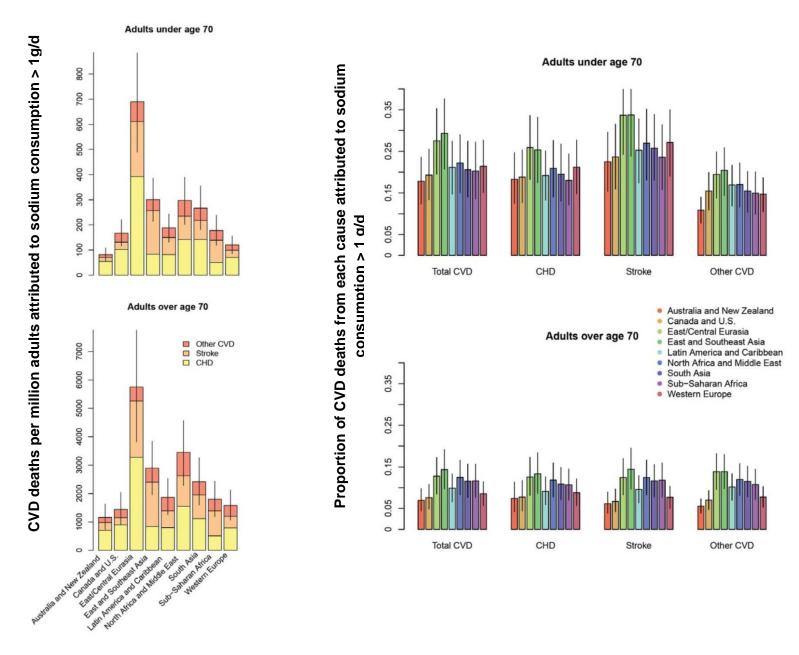

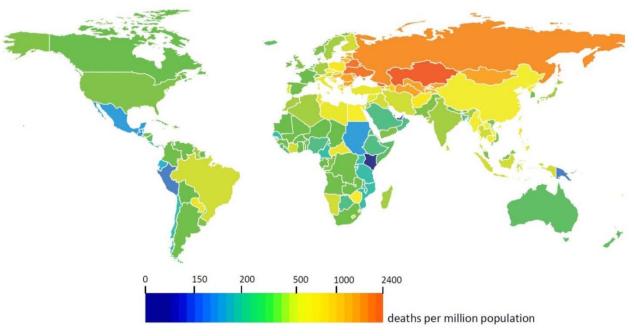

Figure S7. Absolute CVD mortality (deaths per million adults per year) and proportional CVD mortality (percent of all CVD deaths) attributed to sodium consumption >1 g/d in 2010, by age and world region.

Absolute CVD Mortality Attributed to Sodium Intake > 1g/day in 2010

Proportional CVD Mortality Attributed to Sodium Intake > 1g/day in 2010

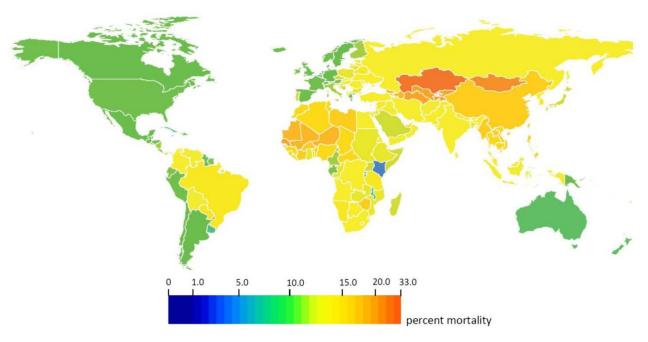

Figure S8. Absolute CVD mortality (deaths per million adults) and proportional CVD mortality (percent of all CVD deaths) attributed to sodium consumption >1 g/d in 2010, by nation.

Table S1. Data sources, modeling approaches, and validation methods used to estimate adult sodium consumption levels, their effects on CVD, and total cause-specific mortality by country, age and sex.

Data sources	Adult (age 20+) population	Statistical methods used for pooling and modeling data from diverse global sources

Household availability surveys Relative risks by age and sex		sources and model missing data using informative time-varying covariates, borrowing information across geographical region and time period while also incorporating uncertainty due to measurement error and model specification. Models were fit using a randomized MCMC algorithm based on the Adaptive Metropolis step function.	Agriculture Organization (FAO) food balance sheets which capture a country's net annual food availability based on reported local production, imports and exports. We used factor analysis to reduce 22 FAO food items representing the majority of food available for human consumption in 187 countries into four factor variables which were included in the model to improve country-level predictions. In addition, we included lag-distributed GDP per capita as a model covariate.						
Effects of sodium on SBP									

Original meta-analysis of 103 randomized controlled trials of sodium reduction on systolic blood pressure (SBP).	Data were from randomized controlled trials conducted worldwide with a total of 107 comparison groups, comprising 6,970 subjects.	The association of change in SBP with change in sodium consumption was assessed using multivariate linear regression incorporating analytic weights to give more weight to observations with less uncertainty.	Age, race (black vs. non-black), and hypertensive status (SBP ≥ w 140 vs. SBP < 140) were included in the model.	Only randomized controlled feeding trials with duration of at least one week, mean sodium reduction of at least 20 mmol/d, and balanced concurrent interventions were included.
Effects of SBP on CVD				
Published pooled analysis of 2 international pooling projects (APCSC, PSC) †	Data were from East Asian, North American, and European pooling projects comprising a total of 99 cohorts, 1.38 million participants, and 65,000 CVD events.	Relative risks from the pooling projects were interpolated and extrapolated into standard age groups using log-linear models. Age-specific relative risks were pooled using random-effects models. Trends in age-specific relative risks from pooled analyses were compared to trends in original cohort data to ensure validity of pooled results.	Effect modification by race/ethnicity and sex were assessed but were not found to be statistically significant.	Trends in age-specific relative risks from pooled analyses were compared to trends in original cohort data to ensure validity of pooled results. The I ² test did not reveal significant heterogeneity between studies for any age group.

Table S3. Evidence used to derive reference intake levels of sodium consumption for adults.

Mean intakes associated with better outcomes

614 mg/d *	Lower systolic BP and lower age-BP slopes in ecologic studies ³⁷
1245 mg/d †	Lower incidence of gastric cancer in meta-analysis of prospective cohorts ³⁹
1500 mg/d	Reduced BP in randomized controlled trials ³⁸
2391 mg/d †	Lower incidence of total stroke in meta-analysis of prospective cohorts ²⁵
2245 mg/d †	Lower incidence of stroke mortality in meta-analysis of prospective cohorts ²⁵
1787 mg/d †	Lower incidence of CHD mortality in meta-analysis of prospective cohorts ²⁵

Lowest age-standardized national mean intakes 40

1480 mg/d	Kenya
1600 mg/d	Rwanda
1660 mg/d	Malawi

Major dietary guidelines

< 1200 mg/d	UK National Institute for Health and Clinical Excellence, 2025 target ¹⁹
< 1500 mg/d	American Heart Association ²⁰
< 1500 mg/d	US Dietary Guidelines Advisory Committee ²¹
< 2300, <1500 mg/d‡	US Dietary Guidelines for Americans ²²
< 2400 mg/d	UK Food Standards Agency ²³
< 2000 mg/d	World Health Organization ²⁴

^{*}Based on the mean of the four populations with the lowest intakes in Intersalt, with results averaged to minimize potential bias or lack of generalizability from using only one population with the lowest intake. †The mean of the median (or midpoint) intakes in the lowest category of risk across all studies for each outcome. For studies in which only the upper limit of the lowest category was reported, we conservatively estimated the median by assuming the range in that category was the same as the range in the next (second) category.

‡2300 mg/d for younger and healthy individuals; 1500 mg/d for adults age 51 years or older and those of any age who are African American or who have hypertension, diabetes, or chronic kidney disease. BP=blood pressure. CHD=coronary heart disease.

^{*}The numbers of deaths in each subtype may not exactly sum to the total CVD deaths due to rounding.

Australia/New Zealand: Australia, New Zealand.

East/Central Eurasia: Albania, Armenia, Azerbaijan, Bulgaria, Bosnia and Herzegovina, Belarus, Czech Republic, Estonia, Georgia, Croatia, Hungary, Kazakhstan, Kyrgyzstan, Lithuania, Latvia, Moldova, Macedonia, Montenegro, Mongolia, Poland, Romania, Russian Federation, Serbia, Slovakia, Slovenia, Tajikistan, Turkmenistan, Ukraine, Uzbekistan

East/Southeast Asia: Brunei Darussalam, China, Fiji, Micronesia, Indonesia, Iapan, Cambodia, Kiribati, Republic of Korea, Lao People's Democratic Republic, Sri Lanka, Maldives, Marshall Islands, Myanmar, Malaysia, Philippines, Papua New Guinea, Democratic People's Republic of Korea, Singapore, Solomon Islands, Thailand, Timor-Leste, Tonga, Taiwan, Viet Nam, Vanuatu, Samoa.

Latin America/Caribbean: Argentina, Antigua and Barbuda, Bahamas, Belize, Bolivia, Brazil, Barbados, Chile, Colombia, Costa Rica, Cuba, Dominica, Dominican Republic, Ecuador, Grenada, Guatemala, Guyana, Honduras, Haiti, Jamaica, Saint Lucia, Mexico, Nicaragua, Panama, Peru, Paraguay, El Salvador, Suriname, Trinidad and Tobago, Uruguay, Saint Vincent and the Grenadines, Venezuela.

North Africa/Middle East: United Arab Emirates, Bahrain, Algeria, Egypt, Iran, Iraq, Jordan, Kuwait, Lebanon, Libyan Arab Jamahiriya, Morocco, Oman, Occupied Palestinian Territory, Qatar, Saudi Arabia, Syrian Arab Republic, Tunisia, Turkey, Yemen. South Asia: Afghanistan, Bangladesh, Bhutan, India, Nepal, Pakistan.

Sub-Saharan Africa: Angola, Burundi, Benin, Burkina Faso, Botswana, Central African Republic, Côte d'Ivoire, Cameroon, Democratic Republic of the Congo, Congo, Comoros, Cape Verde, Djibouti, Eritrea, Ethiopia, Gabon, Ghana, Guinea, Gambia, Guinea, Gambia, Guinea, Kenya, Liberia, Lesotho, Madagascar, Mali, Mozambique, Mauritania, Mauritius, Malawi, Namibia, Niger, Nigeria, Rwanda, Sudan, Senegal, Sierra Leone, Somalia, São Tomé and Príncipe, Swaziland, Seychelles, Chad, Togo, United Republic of Tanzania, Uganda, South Africa, Zambia, Zimbabwe.

Western Europe: Andorra, Austria, Belgium, Switzerland, Cyprus, Germany, Denmark, Spain, Finland, France, United Kingdom, Greece, Ireland, Iceland, Israel, Italy, Luxembourg, Malta, Netherlands, Norway, Portugal, Sweden.

[†]In 2010 globally, there were 14,669,000 total CVD deaths, 6,963,000 CHD deaths, 5,798,000 stroke deaths, and 1,909,000 other CVD deaths.

[‡]Income categorizations based on the World Bank classification system (http://data.worldbank.org/about/country-classifications/country-and-lending-groups).
