Supplementary Online Content

This supplementary material has been provided by the authors to give readers additional information about their work.

eAppendix 1. Criteria for Grading the Evidence of Associations of Specific Dietary Factors on Cardiometabolic Outcomes

The following principles, focusing on meta-analyses of prospective cohort studies and/or randomized controlled trials, guided the scoring for each of 9 Bradford-Hill criteria:[green square] Consistent evidence from several well-designed studies with relatively few limitations;[orange square] Consistent evidence from several studies but with some important limitations; [red square] Emerging evidence from a few studies or conflicting results from several studies; - criterion not met. Definitions for each of the 9 criteria and adaptations to the general scoring system were as follows:

1.   **Strength:** magnitude of association, including RRs for protective factors of >0.9 ([red square]), 0.8-0.89 ([orange square]), or <0.8 ([green square]); and for harmful factors, of <1.11 ([red square]), 1.25 ([orange square]), and >1.25 ([green square]). Since magnitude is directly dependent on both the selected serving size and frequency of consumption, we utilized serving sizes most similar to standard dietary guidelines and frequencies of consumption representing modest, standardized differences in intake (e.g., 1 serving/d of fruit) that are easily communicated and could be feasibly achieved by an intervention.

2.   **Consistency**: association is repeatedly observed in different populations and circumstances, including ≥80% of included study-specific estimates being in the expected direction ([green square]; ≥60 - <80% ([orange square]); ≥40 - <60% ([red square]); and <40% (not meeting criteria). (Though some other grading frameworks use statistical heterogeneity, this is not optimal to assess consistency as characterized by Bradford-Hill. Statistical measures of heterogeneity are influenced by both magnitudes of differences and also the numbers of studies and precision of each estimate. Thus, diet-disease relationships with few studies could have lack of consistency but fail to achieve statistical heterogeneity due to low power; while diet-disease relationships having many studies with high precision could exhibit statistical heterogeneity yet still be consistent in terms of their overall inference for the effect of the dietary factor on disease.)

3.   **Temporality:** exposure precedes outcome. Because all evidence was based on longitudinal studies, this was a necessary criterion ([green square]); when relatively few overall studies were available (<5), we graded this criterion conservatively as [orange square].

4.   **Coherence:** interpretation of association does not conflict with known natural history and biology of the disease, for example based on pathways of disease occurrence and laboratory findings on the dietary factor.

5.   **Specificity:** exposure linked to a specific outcome. Because many nutritional factors can plausibly have diverse effects and influence multiple outcomes, scoring was based on three

principles: 1) dietary factor influences a mechanism/pathways known to cause the outcome; 2) dietary factor not associated with multiple other, unrelated non-communicable diseases (e.g., multiple cancers, chronic obstructive pulmonary disease (COPD)); 3) dietary association has additional specificity within the set of cardiometabolic outcomes (coronary heart disease (CHD), stroke, diabetes mellitus).

6. **Analogy:** based on the effects of similar factors on the disease outcome:

Fruit, vegetables, nuts/seeds: based on analogies with other minimally processed, higher fiber, phytochemical rich foods.

Potatoes: based on analogies to other higher glycemic load carbohydrates in relation to both diabetes mellitus and weight grain (don't want to refer to potatoes as poor-quality carbohydrates).

Whole grains: based on analogies with other less-processed foods, dietary fiber, and glycemic load.

Unprocessed red meat with CVD: based on analogies to dietary heme iron to myocardial infarction and fatal coronary heart disease, L-carnitine, and trimethylamine-N-oxide.

Unprocessed red meat and processed meat with diabetes: based on analogies to processed meats (or unprocessed red meats), blood ferritin levels, and hemochromatosis.

Processed meat with CVD: based on analogies to sodium.

Fish/seafood: based on analogies to omega-3 fatty acids.

Yogurt: based on analogies to probiotics in relation to weight gain.

Chocolate and tea: based on analogies to other polyphenol rich foods.

Milk: based on analogies to other dairy products.

Sugar sweetened beverages, glycemic index, and glycemic load with CVD: based on analogies to other poor-quality carbohydrates in relation to both CVD and weight gain.

Sugar sweetened beverages, glycemic index, and glycemic load with diabetes: based on analogies to other poor-quality carbohydrates in relation to both diabetes mellitus and weight gain.

Polyunsaturated fat: based on analogies to vegetable oils in relation to CHD and cardiovascular risk factors.

Trans-fat: based on analogies to other dietary fats.

Total protein and animal protein: based on analogies to protein rich foods.

Sodium and potassium with CVD: based on analogies to other lifestyle-related and nonlifestyle-related blood pressure interventions and to foods high in sodium (eg, processed meats).

Sodium with blood pressure: based on analogies to potassium.

7. **Plausibility:** association supported by one or more credible biological mechanisms.

8. **Biological gradient:** exposure and outcome are related by a monotonic dose-response curve.

9. **Experiment:** association is also supported by evidence from randomized controlled trials on intermediate risk factors (or, less commonly, disease outcomes) plus supportive laboratory studies.

> Fruit and vegetables: because while strong and consistent evidence from trials of dietary patterns rich in fruits and vegetables, few trials separately evaluated only fruits or vegetables.
>
> Potatoes: based on findings from trials on weight gain and insulin resistance.
>
> Whole grains with diabetes: based on overall effects of carbohydrate quality, including studies of dietary fiber and glycemic load; much less evidence for benefits of whole grains independent of dietary fiber and glycemic load.
>
> Fish with CHD in diabetes patients: based on trials on effects of fish oil supplements on cardiovascular disease in diabetic patients.
>
> Yogurt: based on findings for yogurt and weight gain (animal studies, human cohorts) and for probiotics and weight gain (animal and human experiments).
>
> Chocolate with CVD: based on trials on chocolate and blood pressure.
>
> Tea: based on findings from trials on tea and blood pressure, LDL cholesterol or glycemic response.

Following grading of Bradford-Hill criteria, the characterization of overall sufficient probable or convincing evidence for each diet-disease relationship was based on independent review by two investigators (VM, DM) of the overall findings across the Bradford-Hill criteria,[1] with additional guidance from other definitions for probable or convincing evidence of causality from the WHO and WCRF/AICR;[2-4] any differences were resolved by consensus.

eMethod. Searches for Identifying Meta-analyses of the Associations of Specified Dietary Risk Factors on Cardiometabolic Diseases

For each identified diet-disease relationship, we performed multiple systematic searches of PubMed to identify meta-analyses of randomized controlled trials or prospective cohort studies evaluating these specific dietary factors and total cardiovascular disease, coronary heart disease, stroke including subtypes (ischemic, hemorrhagic), or diabetes. For sodium, and sugar-sweetened beverages and non-nutritive sweetened beverages, we also reviewed effects on blood pressure and obesity, respectively, based on randomized trials demonstrating primary effects on these risk pathways. We did not search for individual papers/studies across multiple dietary risk factors and outcomes, rather we only included published, peer-reviewed meta-analyses. Based on our and other recent reviews[5,6], we did not include multiple other factors for which the initial appraisal identified one or more key limitations that would limit meeting the criteria for quality of evidence. Due to the multiple dietary factors evaluated, a formal listing of the specific reasons for the exclusion of each was not recorded. For each included meta-analysis, we extracted the multivariable-adjusted effect estimate and corresponding 95% confidence intervals (CIs), which generally included major confounders, and did not recalculate the effect estimate by including only adjusted estimates or individual studies adjusting for certain confounders.

eAppendix 2. PubMed Search Terms

<u>**Limits:**</u>

Age: Any

Setting: Any country

Year Range: Any

Language: English

Species: Human

Type of Article: Meta-Analysis [ptyp] OR Meta-Analysis [tiab] OR "Systematic Review"[tiab]

Note: if a search term exists as Mesh, then use both ([mesh] OR [tiab]); if only free-text searching (i.e., no Mesh) then use [tiab]

Date: May/1/2015 through February/26/2021 for all diet factors

Dietary Factors:

Foods

Fruits

Fruit juices

Vegetables

Potatoes

Beans/legumes

Nuts/seeds

Whole grains

Refined grains

Milk

Yogurt

Cheese

  Unprocessed red meats

  Processed meats

  Fish/seafood

Total fish/seafood

Lean fish

Fatty fish

Eggs

Sugar-sweetened beverages

Non-nutritive sweetened beverages

Coffee

Tea

Cocoa (chocolate)

Nutrients

Dietary fatty acids

Polyunsaturated fats (PUFA)

Saturated fats (SFA)

Monounsaturated fats (MUFA)

Seafood omega-3 fats

Plant omega-3 fats

Trans fats

Dietary protein

   Total protein

   Animal protein

   Plant protein

Dietary cholesterol

Dietary fiber

      Total fiber

   Cereal fiber

   Fruit fiber

   Vegetable fiber

   Legume fiber

Glycemic index (GI)

Glycemic load (GL)

Dietary sodium

Dietary potassium

Dietary calcium

  Energy

Outcomes:

Total or non-fatal cardiovascular disease (CVD)

Total or non-fatal coronary heart disease (CHD), coronary artery disease (CAD) or ischemic heart disease (IHD)

Total or non-fatal myocardial infarction (MI)

Total or non-fatal stroke

Total or non-fatal ischemic stroke

Total or non-fatal hemorrhagic stroke

Type II diabetes mellitus

Change in body mass index (BMI) [sugar-sweetened beverages and non-nutritive sweetened beverages only]

Systolic blood pressure (SBP) [sodium only]

Diastolic blood pressure (DBP) [sodium only]

Inclusion Criteria

1.   **Study Design:** Systematic review/meta-analysis of prospective cohort studies (including nested case-control design) or randomized controlled trials.

2.   **Population:** General adult human population 18 years or older; adult populations with prediabetes, insulin resistance, metabolic syndrome, hypertension, overweight or obesity; adults with type 2 diabetes (CVD outcomes only).

3.   **Exposure:** Intake of specified dietary factors, either continuous or in >2 categories of intake to allow for adequate categorization of intake.

4.   **Outcome:** Incident (fatal or non-fatal) of specified cardiometabolic health outcomes.

5.   **Effect Estimate:** Multi-variate adjusted effect estimate (OR, RR, HR) and variance.

6.   **Setting:** No restrictions on type of setting applied.

7.   **Language:** English.

8.   **Publication type:** Full text, published, peer reviewed.

Exclusion Criteria

1.   **Study Design:** Systematic review/meta-analysis of retrospective case-control studies; pooling studies/genome-wide association studies (GWAS).

2.   **Population:** Younger than 18 years old, pregnant women, children, and specified diseased (e.g., end-stage or rare diseases) or special (e.g., vegetarians vs. non-vegetarians) populations.

3.   **Exposure:** mixed healthy diet was reported, where the individual dietary factor could not be separated; dietary supplementation or biomarker studies/trials.

4.   **Outcome:** Studies of prevalence of outcome, studies of intermediate risk factors to the outcomes of interest (e.g., lipids, hypertension).

5.   **Effect Estimate:** unadjusted (crude) risk estimates only.

6.   **Number of primary studies:** <3 individual studies in the dose-response meta-analysis.

7.   **Duplicate Publications:** When duplicate publications were identified, the report on the largest number of cases for each endpoint of interest and/or most recent search date was included.

4 Retracted or duplicate study

Studies meeting inclusion criteria (n=97)

Included

97 Studies included
(158 diet disease relationships from dose-response meta-analyses)

eFigure 2. Estimates of Etiologic Associations of Sodium and Systolic Blood Pressure

Source	Dietary Factor	Outcome	Studies in Each Meta−analysis	No. of Subjects	No. of Events	Unit		mm HG (95% CI)	I²
Mozaffarian 2014	Sodium	SBP, main effect, white, age 50, normotensives	103 RCTS (107 estimates)	6,970	N/A	per 2,300 mg/d (100 mmol/d)		3.74 (5.18, 2.29)	NR
Mozaffarian 2014	Sodium	SBP, additional effect per year of age < or > 50	103 RCTS (107 estimates)	6,970	N/A	per 2,300 mg/d (100 mmol/d)		0.105 (0.164, 0.047)	NR
Mozaffarian 2014	Sodium	SBP, additional effect among Blacks	103 RCTS (107 estimates)	6,970	N/A	per 2,300 mg/d (100 mmol/d)		2.49 (4.85, 0.13)	NR
Mozaffarian 2014	Sodium	SBP, additional effect among hypertensives	103 RCTS (107 estimates)	6,970	N/A	per 2,300 mg/d (100 mmol/d)		1.87 (3.63, 0.12)	NR

Change in SBP (mm Hg (95% CI))
−0.5 0.5 1.5 2.5 3.5 4.5 5.5

The boxes in the plot show the effect estimates from the meta-analyses and the horizontal lines through the boxes show the length of the confidence interval.

NR: Not reported

Dietary factors with probable or convincing evidence, based on the Bradford-Hill criteria, for associations on cardiometabolic (CMD) outcomes including cardiovascular disease (CVD), coronary heart disease (CHD), stroke, and type 2 diabetes. Diet-CMD relationships with <3 studies and papers that did not reference the individual studies included in the dose-response meta-analysis were not included.

Number of estimates can be higher than the number of studies if more than one arm in a randomized controlled trial, if estimates were separated by age or sex in prospective cohort studies, or more than one prospective cohort study was included in a single study.

Although we identified several meta-analyses on the relationship between dietary sodium intake, and SBP and DBP[7-11], no studies adjusted for age-, race-, and hypertension-status interactions which have been shown to mediate the association. For this relationship, we selected the study included in our previous review paper. Available evidence suggest that sodium increases mortality from CHD, stroke, and other-blood pressure related cardiovascular diseases through effects on SBP. For every year above or below age 50, there was 0.105 mm HG (95% CI: 0.047, 0.164) larger or smaller BP reduction, respectively. Effects on CVD vs. SBP were separately identified and are not independent (i.e., effects on CVD are at least partly mediated by SBP effects).

eTable 2. Estimates of Associations of Dietary Factors and Risk of Cardiometabolic Disease (Original Units and RRs [CIs])

Effect sizes (RR and 95% CI) and unit of RR as reported by the published meta-analysis.

PUFA: polyunsaturated fats; CHO: carbohydrates; SFA: saturated fat; %E/d: percent energy per day.

NR: Not reported

Dietary factors with probable or convincing evidence, based on the Bradford-Hill criteria for assessing causality, for associations on cardiometabolic (CMD) outcomes including cardiovascular disease (CVD), coronary heart disease (CHD), stroke, and type 2 diabetes. Diet-CMD relationships with <3 studies and papers that did not reference the individual studies included in the dose-response meta-analysis were not included.

Fruits- exclude 100% juices, and vegetables exclude vegetable juices, starchy vegetables such as potatoes and corn, and salted or pickled vegetables. Because individual studies may include potatoes in the vegetable category, the associations identified for vegetables should be considered as representing the outcome of vegetables, including potatoes. Associations of potatoes were also evaluated separately.

Evidence suggests that SSBs are associated with increased risk because they affect both BMI and BMI-independent factors of type 2 diabetes and cardiovascular outcomes. Several meta-analyses found an association between SSB intake and incident overweight or obesity, but none reported on the association between changes in SSB intake and weight gain. For this association, we selected a pooled analysis of 3 prospective cohort studies[29].

© 2022 Miller V et al. *JAMA Network Open.*

Glycemic load is calculated as the glycemic index of a food multiplied by its carbohydrate content. Higher values reflect both higher glycemic index and higher quantities of refines grains, starches, and sugars. Evidence of associations of dietary fiber was also identified. Glycemic load and dietary fiber overlap with foods in Figure 2, including fruits, vegetables, potatoes, beans or legumes, nuts or seeds, whole grains, and refined grains. Although the Reynolds et al[31] meta-analysis contained 1 additional primary study than Livesey et al[34], we did not select it because it included several primary studies with poor dietary instrument validity that resulted in a null association between glycemic index and diabetes.

Sodium was assessed by 24-hr dietary recall, food frequency questionnaire, or 24-hr urine excretion.

No meta-analyses were identified for potassium. For this association, the study identified in the previous review[6] was selected.

eTable 3. Reasons for Excluding Dietary Factor-CMD Relationships

Dietary Factor	Outcome	Reason(s) for Exclusion
Beans/legumes[42]	CVD	Consistency could not be assessed because the meta-analysis did not reference the primary studies or include a forest plot
Nuts/seeds[43]	Hemorrhagic stroke	Consistency could not be assessed because the meta-analysis did not reference the primary studies or include a forest plot
Fruit juice[44]	CVD	<3 primary studies included in the meta-analysis
	Stroke	<3 primary studies included in the meta-analysis
SSBs[45]	MI	<3 primary studies included in the meta-analysis
Non-nutritive sweetened beverages[27,28]	CVD	Lack of biological plausibility, and supportive experiment from RCTs and cohorts of risk factors
	CHD	Lack of biological plausibility, and supportive experiment from RCTs and cohorts of risk factors
	Stroke	Lack of biological plausibility, and supportive experiment from RCTs and cohorts of risk factors
	Diabetes	Lack of supportive experiment, including from RCTs and cohorts of risk factors
Vegetable fiber[31]	CHD	<3 primary studies included in the meta-analysis
PUFA[46]	CVD	Lack of biological plausibility, and supportive experiment from RCTs and cohorts of risk factors
PUFA replacing SFA[47]	CVD in diabetes patients	<3 primary studies included in the meta-analysis
MUFA replacing CHO[36]	Diabetes	Lack of biological plausibility, and supportive experiment from RCTs and cohorts of risk factors
Coffee[48]	Diabetes	Lack of supportive experiment, including from RCTs and cohorts of risk factors
SFA[49,50]	CVD	Included trials were mostly PUFA replacing SFA
	Stroke	Lack of biological plausibility
	Hemorrhagic stroke	Consistency could not be assessed because the meta-analysis did not reference the primary studies or include a forest plot
Sodium[51]	CVD	Consistency could not be assessed because the meta-analysis did not reference the primary studies or include a forest plot

Although meta-analyses were available for several diet-CMD relationships, no significant associations were found, such as eggs[52,53], SFA[36,46,54], milk[22,26,55,56], legumes[17,19,42], refined grains[15,17,19], nuts[14,17,43], MUFA[36,46,47,54], cheese[22,55,56], and yogurt[55,56].

Our updated search did not identify dose-response meta-analyses on lean fish, fatty fish, seafood omega-3, plant omega-3, dietary cholesterol, dietary calcium, or total energy.
